

# plant functional types

“How can the diversity of species and their responses to climate change variables be effectively simplified for modelling purposes?”

Version for use toward synthesis document: with unpublished data removed

Two main sources of information

- Macquarie Uni comparative ecology group, including
  - Ian Wright, trait correlations and leaf physiology
  - Fiona Scarff, flammability
  - Dan Falster, height and strategy mixtures
  - Anna Richards, C-N relations
- ARC-NZ Research Network for Vegetation Function
  - Collaborating with UK-QUEST (Quantifying and Understanding the Earth System) for vegetation modeling
  - Various working groups synthesizing data

# In LPJ there are ~10 basic PFTs, differentiated on

- Photosynthetic and respiration traits:  $V_{cmax}$ ,  $J_{max}$ , etc
- Woody vs herbaceous; evergreen vs raingreen vs winter-deciduous; C3 vs C4
- climate zone restrictions: GDD, cold-month T, warm-month T
- Scaling relations among dbh, height, total leaf area, crown width
- LMA, leaf lifespan
- $C_i/C_a$ ,  $E_{max}$

# Three styles of development

- Improved parameters for existing PFTs
- Add more PFTs
  - Further subdividing the range of responses
  - Ecosystem Demography
  - Fire and fire-response PFTs in Australasia
- Evolutionary Ecology Vegetation Model
  - Derive ecol and evol stable strategy mixture

# PFT-trait parameterization: key traits vary continuously, often as correlated axes

- E.g. “leaf economic spectrum”
- leaf N,  $A_{\max}$ ,  $R_d$ , leaf lifespan, leaf mass per area
- Nearly 80% of worldwide variation is along the main axis

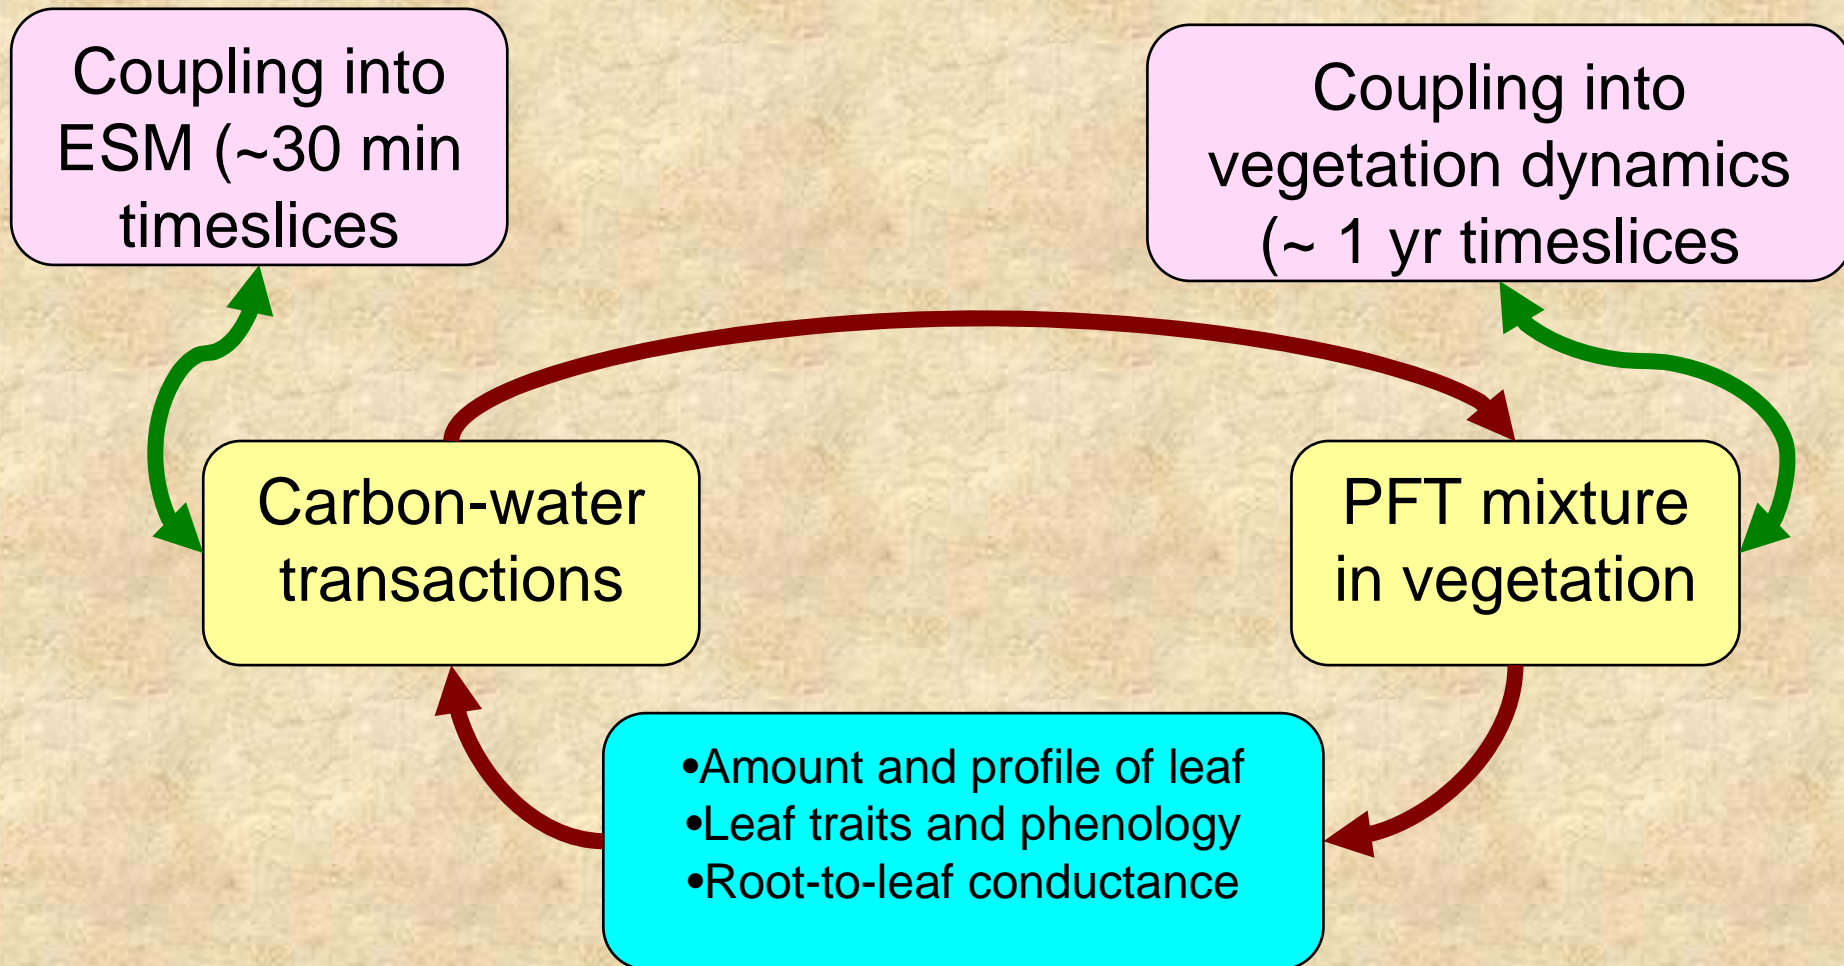

Image unavailable

Squares show  
Sheffield DGVM  
PFTs, against  
background of actual  
species mainly from  
Glopnet

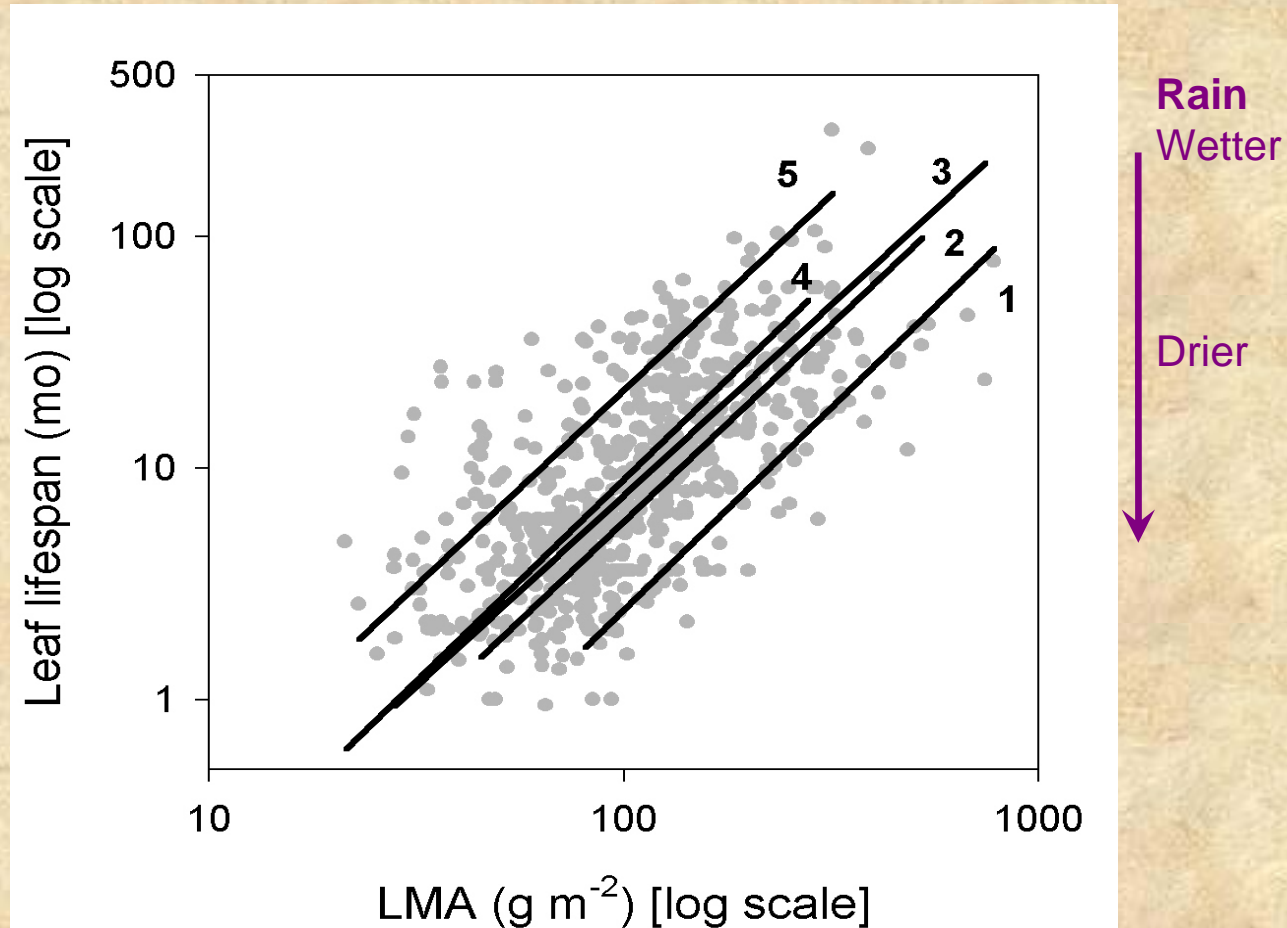

- Correlation across PFT's loosely reflects correlation across real species
- PFT traits are sometimes near centroid of species, sometimes not
- note wide range within each PFT, and continuous variation

# PFTs could be much more numerous for vegetation dynamics, but would need to be condensed for coupling to ESM

Some pairwise trait relationships are modulated by climate; could replace parameters with appropriate equations

# Replacing set parameters for each PFT by appropriate equations in DGVMs

- Coordination between traits
- Modulating with physical environment
- Trials in Sheffield DGVM
  - in collaboration with Rosie Fisher (UK-QUEST)

# Ecosystem Demography

- ‘size and age structured approximation’: method of grouping similar trees together, to reduce computational load
  - Trees grouped into classes by **PFT**, **height**, and **age since last disturbance**
- being implemented by Rosie Fisher (Sheffield) into JULES, for gap-phase succession in Amazon
- Veg Function Network and QUEST are collaborating to assemble test data sets in a wide range of vegetation types

Image unavailable

Mortality vs wood density,  
as implemented into ED  
for Amazon forests  
by Rosie Fisher

# Other parameters: decompositio n and fire

# WG20 meta-analysis of multi-species decomposition trials

Image unavailable

Diameter shows range across climate zones within species

Diameter shows range across species

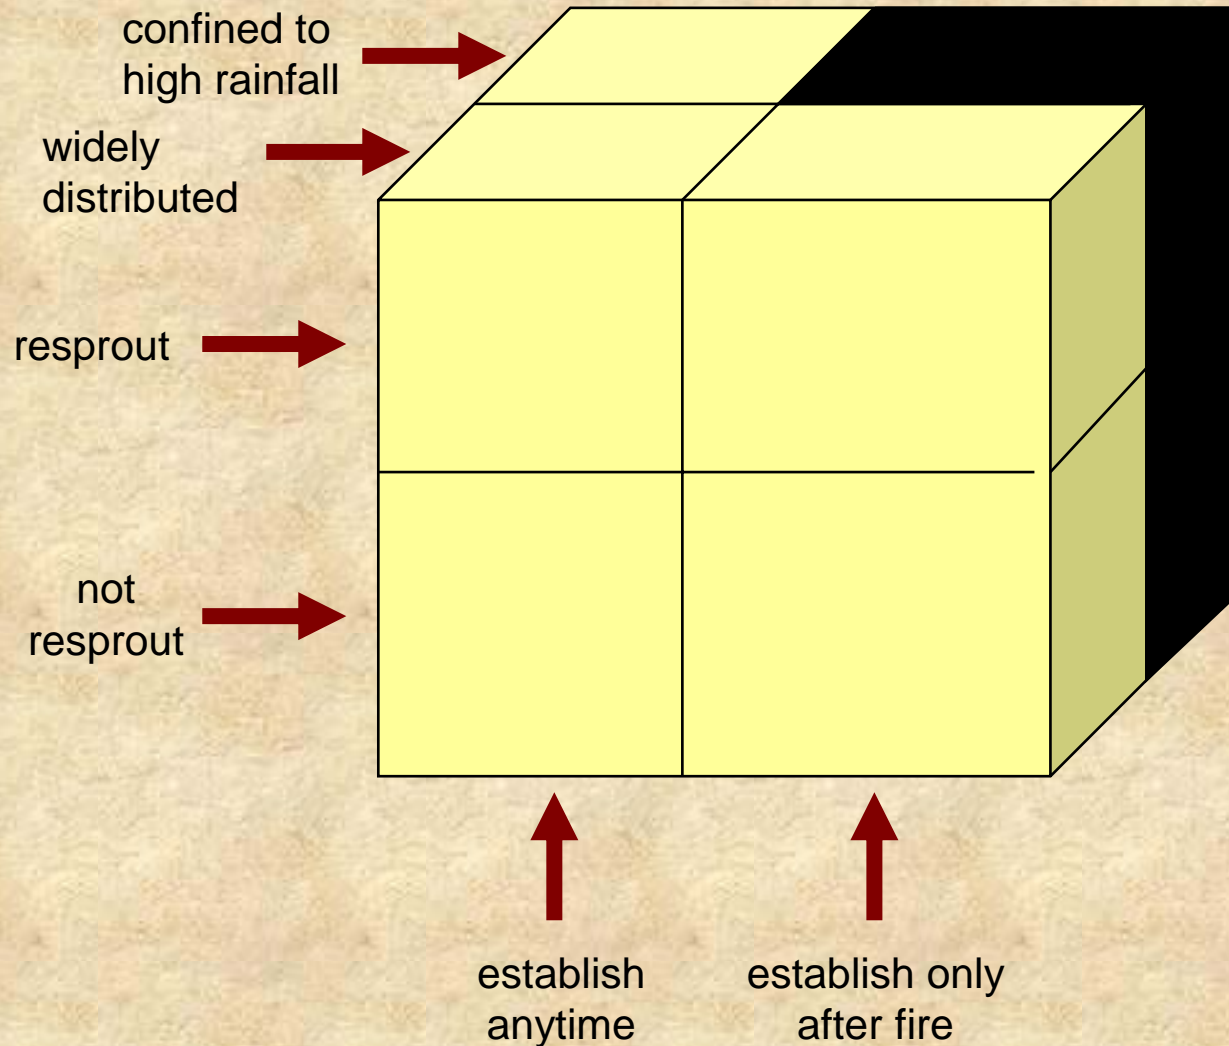

# WG24 Fire, vegetation and climate change in Australasia (collab with QUEST-UK)

- Compile palaeo database for Australasian quaternary vegetation
- New set of PFTs for fire modeling in Australian vegetation
- Classify Australian pollen-types into PFTs
- Apply into LPJ-Spitfire, simulate fire and vegetation at various key times in the past, compare to maps from palaeodatabase

# WG24 currently adopting 2 x 2 x 2 classification for woody plants in relation to fire

# PFTs for Australia?

- Triodia

- grasses that accumulate as fuel generating fire-regimes like shrub-dominated vegetation

T spicata  
on hilltops

T  
longiceps

T pungens  
(5-10 yr  
after fire)

T pungens  
(1-2 yr  
after fire)

# PFTs for Australia (cont)?

- Eucalypts
  - Maintain fast transpiration even during dry season?

# PFTs for Australia (cont)?

- Nutrient acquisition strategies (cluster-roots, AM/Ecto/Ericoid, N-fixers)
  - Become relevant when models have better soil landscapes or nutrient cycles
  - Old, low-P soils generally seen as a key feature of Australian ecology
    - And an opportunity to improve representation also of other substantial parts of the world

Image unavailable

# PFTs for Australia? (cont)

- Crops?
- Vegetation types rather than PFTs
- Dynamics of coverage not decided by competitive growth
- Still, there could be several benefits from including in modeling

# Evolutionary Ecology Vegetation Model (EEVM)

- Current DGVMs have PFTs with fixed traits
- An EEVM would instead evolve plants with whatever trait-combinations were most successful
- Potential benefits include
  - Flexible and continuous variation across modeled plants
  - Follow evolutionary response to changing conditions
  - Including evolutionarily novel conditions such as high CO<sub>2</sub>

# nature of an Evol Ecol Veg Model

- Traits would be allowed to “float” under natural selection until they settled, giving predicted PFTs
  - integrated test of scattered collection of theory about how trait-values are positioned by natural selection
- The PFT-mixture would be predicted at evolutionary and ecological equilibrium
  - Not coupled to an earth system model
  - Does not deal with “transients”, progressive change as the environment changes
  - It would, however, build scenarios for the end-points towards which selection might be heading
- Complementary to DGVMs rather than replacing them

# Two strands

1

Strategy-mixture  
along a single tradeoff

- need a “fast solver” based on adaptive dynamics

Apply to different tradeoffs, e.g. height, time since disturbance

2

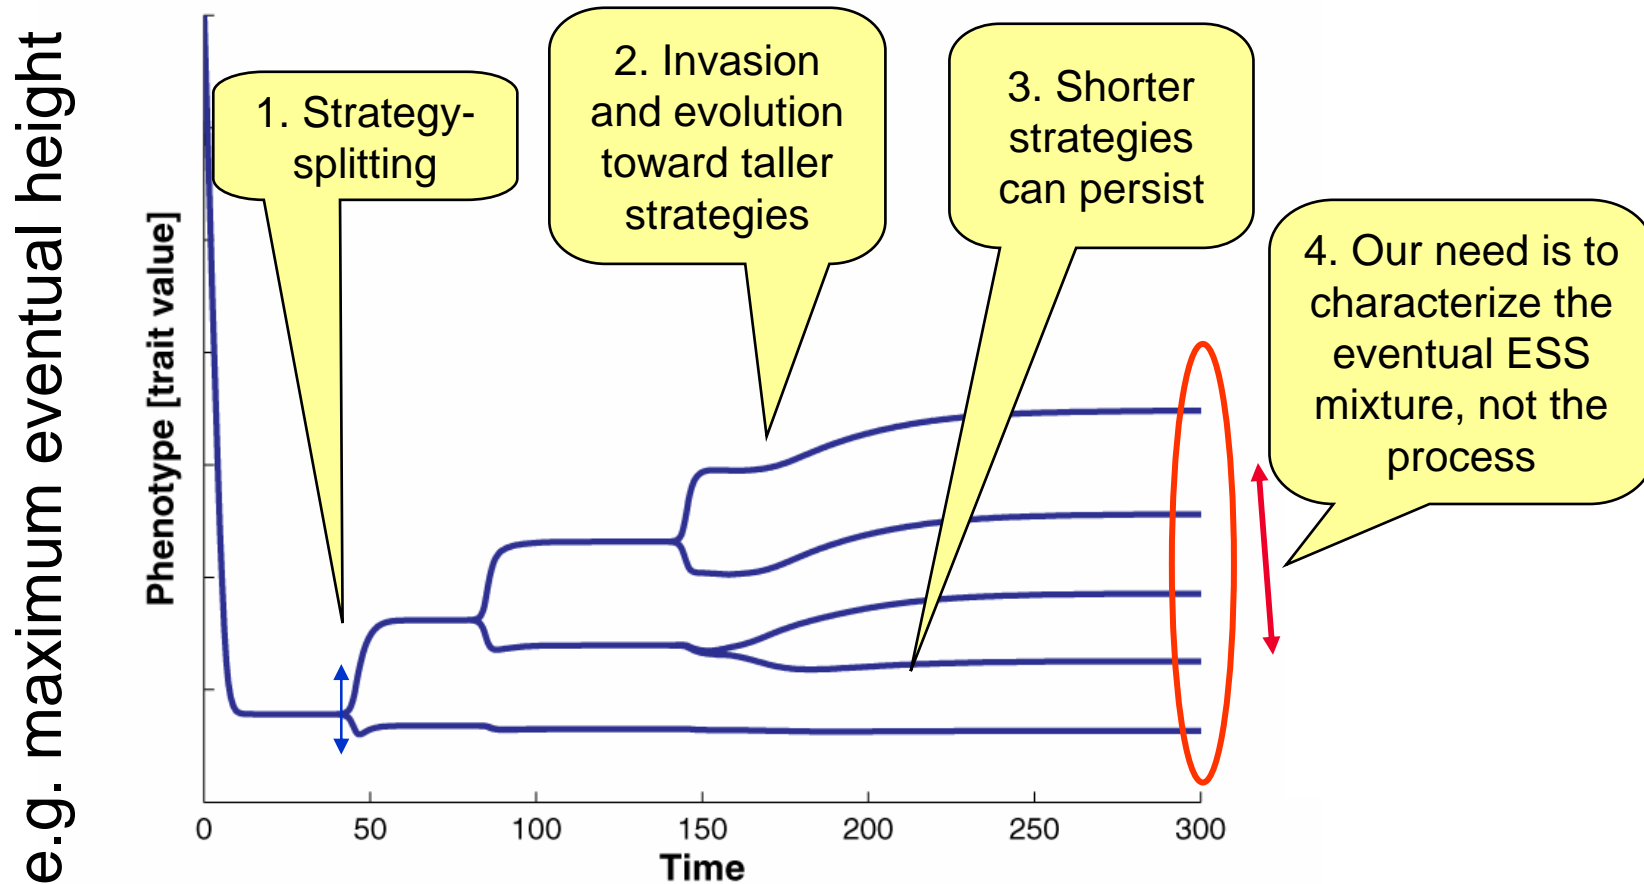

Optimization of traits  
where there should be  
a single best solution  
under given  
irradiance, VPD etc

Image unavailable

Optimum sapwood area per leaf area in relation to physical-environment variables (Westoby, Falster, Cornwell in prep). What has been optimized here is [revenue - cost] per leaf area.

# Emergence of an ESS strategy-mixture through “adaptive dynamics”

Doebeli, M. & Dieckmann, U. (2000) Evolutionary branching and sympatric speciation caused by different types of ecological interactions. *American Naturalist*, 156, S77-S101.

de Mazancourt, C. & Dieckmann, U. (2004) Trade-off geometries and frequency-dependent selection. *American Naturalist*, 164, 765-778.

# Timelines for different styles of development

- Improved parameters for existing PFTs
  - Possible over next 1-2 years, continuing thereafter
- Add more PFTs
  - Possible over next 1-2 yr, continuing thereafter
- Evolutionary Ecology Vegetation Model
  - Maybe 5-8 years off?
